A desalination system is provided. The desalination system comprises a desalination apparatus. The desalination apparatus comprises first and second electrodes, and a first group of paired ion exchange membranes disposed between the first and second electrodes to form a first group of alternating first and second channels. The first channels are configured to receive a first stream for desalination and the second channels are configured to receive a second stream to carry away ions removed from the first stream, respectively. The desalination apparatus further comprises a plurality of spacers disposed between each pair of the adjacent ion exchange membranes and between the first and second electrodes and the respective ion exchange membranes. Wherein each of the ion exchange membranes in the first group is a cation exchange membrane. A desalination system and a method for removing ions from an aqueous stream area also presented.

FIG. 4

DESALINATION SYSTEM AND METHOD

BACKGROUND OF THE DISCLOSURE

The invention relates generally to desalination systems and methods for pure water production. More particularly, this invention relates to desalination systems and methods using ion exchange membranes for removal of hardness ions for high purity water production.

Water with high purity are widely used in in many industrial processes, such as in high-pressure boilers in power plants, production of semiconductor elements, production of printed circuit boards, production of integrated circuit, and production of injection water for medical purpose.

Typically, due to continuous operation, and stable and relatively higher quality of product water, electrodeionization (EDI) apparatuses have been employed for processing such liquid streams, for example for production of pure water. Generally, the EDI apparatuses use conventional electro dialysis systems with ion exchange resin filled therein to process the liquid streams. However, during operation, because polyvalent cations with higher concentration may cause scaling tendency, the EDI apparatuses have a hardness tolerance for the liquid streams to be processed. For example, the hardness tolerance of the EDI apparatuses is about less than 1 ppm, which may need rigorous pretreatment of the liquid streams to decrease the hardness therein before the liquid streams are introduced into the EDI apparatus.

There have been attempts to pretreat the liquid streams to decrease the hardness therein. For example, reversal osmosis (RO) apparatuses are employed. However, the processing efficiency of the reversal osmosis apparatuses may be relatively lower for decreasing the hardness in the liquid streams to a certain level suitable for the EDI apparatuses. As a result, the processing cost may be increased accordingly.

Therefore, there is a need for new and improved desalination system and method for removal of hardness ions for high purity water production.

BRIEF DESCRIPTION OF THE DISCLOSURE

A desalination system is provided in accordance with one embodiment of the invention. The desalination system comprises a desalination apparatus. The desalination apparatus comprises first and second electrodes, and a first group of paired ion exchange membranes disposed between the first and second electrodes to form a first group of alternating first and second channels. The first channels are configured to receive a first stream for desalination and the second channels are configured to receive a second stream to carry away ions removed from the first stream, respectively. The desalination apparatus further comprises a plurality of spacers disposed between each pair of the adjacent ion exchange membranes and between the first and second electrodes and the respective ion exchange membranes. Wherein each of the ion exchange membranes in the first group is a cation exchange membrane.

A desalination system is provided in accordance with another embodiment of the invention. The desalination system comprises a desalination apparatus configured to remove hardness ions from an aqueous stream. The desalination apparatus comprises first and second electrodes, and a first group of paired ion exchange membranes disposed between the first and second electrodes to form a first group of alternating first and second channels to receive a first feed

stream for removal of the hardness ions and a second feed stream to carry away the hardness ions removed from the first feed stream respectively. The desalination apparatus further comprises a second group of the paired ion exchange membranes disposed between the first group of the ion exchange membranes and at least one of the first and second electrodes to form a second group of the alternating first and second channels, and a plurality of spacers disposed between each pair of the adjacent ion exchange membranes and between the first and second electrodes and the respective ion exchange membranes. Wherein each of the ion exchange membranes in the first group of the paired ion exchange membranes is a cation exchange membrane, and wherein the second group of the paired ion exchange membranes comprises a plurality of alternating cation and anion exchange membranes.

Embodiment of the invention further provides a method for removing ions from an aqueous stream. The method comprises passing a first feed stream through first channels of a first group of alternating first and second channels defined by a first group of paired cation exchange membranes of a desalination apparatus for removing ions to produce a first output stream, and passing a second feed stream through the second channels of the first group of the alternating first and second channels defined by the first group of the paired cation exchange membranes of the desalination apparatus to carry away ions removed from the first feed stream.

These and other advantages and features will be better understood from the following detailed description of embodiments of the invention that is provided in connection with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a schematic diagram of a desalination system in accordance with one embodiment of the invention;

FIG. 2 is schematic diagram of a desalination apparatus in accordance with one embodiment of the invention;

FIG. 3 is an experimental graph illustrating hardness ion removal efficiency of the desalination apparatus in accordance with one embodiment of the invention; and

FIG. 4 is a schematic diagram of the desalination system in accordance with another embodiment of the invention.

DETAILED DESCRIPTION OF THE INVENTION

Embodiments of the present disclosure will be described hereinbelow with reference to the accompanying drawings. In the following description, well-known functions or constructions are not described in detail to avoid obscuring the disclosure in unnecessary detail.

FIG. 1 is a schematic diagram of a desalination system 10 in accordance with one embodiment of the invention. As illustrated in FIG. 1, the desalination system 10 comprises a desalination apparatus 11 and an electrodeionization (EDI) apparatus 12 in fluid communication with the desalination apparatus 11.

In some embodiments, the desalination apparatus 11 is configured to receive a first feed stream 13 having salts or other impurities from a first liquid source (not shown) for desalination and to receive a second feed stream 14 from a second liquid source (not shown) during or after desalination of the first feed stream 13 so as to carry charged species or target ions removed from the first feed stream 13 out of the desalination apparatus 11.

In non-limiting examples, the salts in the first feed stream **13** may include charged ions, such as sodium (Na^+), chlorine (Cl^-), hardness ions including magnesium (Mg^{2+}) and/or calcium (Ca^{2+}), and/or other ions. In one example, the charged ions in the first stream **13** at least include target ions, such as a portion of the hardness ions.

Thus, due to desalination of the desalination apparatus **11**, at least a portion of the charged or target ions including the hardness ions in the first feed stream **13** may be removed. As a result, a first output stream **15** is produced and then may be introduced into the EDI apparatus **12** for further processing, which may be a dilute liquid and have a lower concentration of the charged species, such as the hardness ions as compared to the first feed stream **13**. Meanwhile, a second output stream (a concentrated stream) **16** is also produced, which has a higher concentration of charged species, such as the hardness ions than the second feed stream **14**.

In some applications, the first output stream **15** may be circulated into the desalination apparatus **11** or introduced into any other suitable desalination apparatuses, such as reversal osmosis apparatuses for further processing to remove the charged ions therein before introduced into the EDI apparatus **12**. In certain applications, the EDI apparatus may or may not be employed based on different applications.

As used herein, the term "EDI" means an electrochemical purification process using ion exchange membranes and ion exchange resin to remove target ions or charged species from water or other fluids so as to produce higher quality water, for example, pure or ultrapure water.

In non-limiting examples, the EDI apparatus **12** comprises a pair of electrodes configured to act as an anode and a cathode, respectively. A plurality of alternating anion and cation exchange membranes are disposed between the anode and the cathode to form a plurality of alternating first and second channels therebetween, which are also referred to as dilute and concentrate channels under operating conditions. A plurality of spacers are disposed between each pair of the membranes, and between the electrodes and the respective adjacent membranes, which may be similar to the structure of an electrodialysis (ED) apparatus. Similarly, the anion exchange membrane(s) are configured to be passable for anions. The cation exchange membrane(s) are configured to be passable for cations.

In addition, based on different applications, the ion exchange resin may be filled into the first channels or the second channels for facilitation of transportation of ions, enhancing the conductivity between the adjacent ion exchange membranes, and electrochemical splitting of water. In non-limiting examples, the ion exchange resin may be filled into the first (dilute) channels.

For some arrangements, the electrodes of the EDI apparatus **12** may be in the form of plates that are disposed parallel to each other to form a stacked structure. Alternatively, the electrodes may be arranged in varying configurations. For example, the electrodes may be disposed concentrically with a spiral and continuous space therebetween. In some applications, the electrodes may include electrically conductive materials. The spacers may comprise any ion-permeable, electronically nonconductive material, including membranes and porous and nonporous materials.

In non-limiting examples, the cathode may include stainless steel. The anode may include iridium oxide or platinum coated titanium. The anion exchange membrane may comprise a polymeric material that includes quaternary amine groups. The cation exchange membrane may comprise a polymeric material that includes sulfonic acid groups and/or

carboxylic acid groups. The ion exchange resin may include crosslinked polystyrene or other suitable materials.

Accordingly, during operation, an electrical current is applied to the EDI apparatus **12**. The first output stream **15** from the desalination apparatus **11** is introduced into the dilute channels filled with the ion exchange resin for further removal of the target ions, such as the hardness ions therein so as to produce a product fluid **17** with a higher quality. A third stream **18** from a liquid source (not shown) is introduced into the concentrate channels to carry the removed target ions from the respective dilute channels out of the EDI apparatus **12** so as to produce a concentrate fluid **19**. In certain applications, the product fluid **17** may be circulated into the EDI apparatus **12** for further processing.

Meanwhile, water splitting reactions occur in the ion exchange resin in the first channels to produce H^+ and OH^- for regeneration of the ion exchange resin for facilitation of continuous operation. An electrolyte stream (not shown) may pass through surfaces of the electrodes to remove gases, such as hydrogen and chlorine generated during the operation to protect the electrodes.

Generally, the EDI apparatus **12** has a hardness tolerance for a liquid to be processed therein. For example, the hardness tolerance of the EDI apparatuses may be about less than 1 ppm. In order to decrease the hardness in the liquid to a suitable level so as to alleviate or avoid scaling or fouling tendency in the EDI apparatus **12** during processing, as depicted in FIG. 1, the desalination apparatus **11** is employed to pretreat the first feed stream **13** so as to produce the first output stream **15** having a suitable level of the target ions including, but not limited to the hardness ions.

FIG. 2 illustrates a schematic diagram of the desalination apparatus **11** in accordance with one embodiment of the invention. As illustrated in FIG. 2, the desalination apparatus **11** comprises a first electrode **20**, a second electrode **21**, a plurality of cation exchange membranes **22** and a plurality of spacers **23**. In the illustrated example, the first and second electrodes **20**, **21** are connected to positive and negative terminals of a power source (not shown) so as to act as an anode and a cathode, respectively. Alternatively, the polarity of the first and second electrodes **20**, **21** may be reversed.

In some examples, the first and second electrodes **20**, **21** may include metal materials with different shapes, such as titanium plates or platinum coated titanium plates. In other examples, the first and second electrodes **20**, **21** may include electrically conductive materials, which may or may not be thermally conductive, and may have particles with smaller sizes and large surface areas. In some examples, the electrically conductive material may include one or more carbon materials. Non-limiting examples of the carbon materials include activated carbon particles, porous carbon particles, carbon fibers, carbon aerogels, porous mesocarbon microbeads, or combinations thereof. In other examples, the electrically conductive materials may include a conductive composite, such as oxides of manganese, or iron, or both, or carbides of titanium, zirconium, vanadium, tungsten, or combinations thereof.

In the illustrated example, the first and second electrodes **20**, **21** are in the form of plates that are disposed parallel to each other to form a stacked structure. In other examples, the first and second electrodes **20**, **21** may have varied shapes, such as a sheet, a block, or a cylinder. In addition, the first and second electrodes **20**, **21** may be arranged in varying configurations. For example, the first and second electrodes **20**, **21** may be disposed concentrically with a spiral and continuous space therebetween.

The cation exchange membranes **22** are configured to be passable for cations and are disposed between the first and second electrodes **20**, **21** so as to form a plurality of alternating first and second channels **24**, **25** therebetween, which are also referred to as dilute and concentrate channels under operating conditions, respectively. In the illustrated example, four cation exchange membranes **22** are employed to form one first channel **24** and two second channels **25**, which are disposed alternately. Alternatively, at least three cation exchange membranes **22** may be employed so as to form one or more first channels and one or more second channels between the first and second electrodes **20**, **21**.

In some applications, the cation exchange membranes **22** may comprise normal cation exchange membranes configured to be passable for not only the monovalent anions but also polyvalent anions. In certain applications, based on different applications, for example, for removal of monovalent cations, the desalination apparatus **11** may comprise one or more monovalent cation exchange membranes. Thus, the normal cation exchange membranes and the monovalent cation exchange membranes may be disposed alternately to facilitate removal of the hardness ions. Non-limiting examples of suitable materials for use in the normal cation exchange membranes include a polymeric material that includes sulfonic acid groups and/or carboxylic acid groups, for transmission of the cations.

The spacers **23** are disposed between each pair of two adjacent ion exchange membranes **22**, and between the first and second electrodes **20**, **21** and the respective adjacent membranes **22**. In some embodiments, the spacers **23** may comprise any ion-permeable, electronically nonconductive material, including membranes and porous and nonporous materials.

Accordingly, during operation, when the desalination apparatus **11** is at a normal polarity state, while an electrical current is applied to the desalination apparatus **11**, liquids, such as the first and second streams **13**, **14** are introduced into the first channel **24** and the second channels **25**, respectively. In certain applications, the first and second stream **13**, **14** may or may not be introduced into desalination apparatus **11** simultaneously.

During the first and second stream **13**, **14** pass through the respective dilute and concentrate channels **24**, **25**, due to presence of the cation exchange membranes **22**, in the dilute channel **24**, at least a portion of the target ions, such as Mg^{2+} and Ca^{2+} , and other cations, such as Na^+ in the first feed stream **13** may migrate through the respective cation exchange membranes **22** towards the anode **20** to enter into the concentrate channels **25**. Anions, such as Cl^- in the first feed stream **13** may not migrate through the respective anion exchange membrane and remain in the dilute channel **24**.

In the concentrate channels **25**, anions, such as Cl^- in the second feed stream **14** may not migrate through the anion exchange membrane **22** and remain therein. In certain applications, a portion of the removed target cations, such as Mg^{2+} and/or Ca^{2+} migrated into the concentrate channels **25** from the first feed stream **13** in the dilute channel **24** and other cations, such as Na^+ may further migrate through the cation exchange membranes **22** to enter into the dilute channel(s) **24** from the respective adjacent concentrate channels **25** during operation.

In non-limiting examples, in order to prevent at least a portion of the removed target ions migrated into the concentrate channels **25** from the dilute channels **24** from entering into the dilute channels **24** so as to enter into the first feed stream **13** again, the second feed stream **14** may include active monovalent cations, such as Na^+ (which is

referred to be as Na^+ -rich stream), which may carry at least a larger portion of the ionic current than the target ions migrated into the concentrate channels **25** from the dilute channel **24** when the cations migrate from the concentrate channels **25** to the respective dilute channels **24** during operation.

In non-limiting examples, a concentration of the active monovalent cations may be greater than a concentration of the removed target ions in the respective concentrate channels **25**. In some examples, an ionic mobility of the active monovalent ions may be greater than the ionic mobility of the removed target ions in the respective concentrate channels **25** when migrated from the concentrate channels **25** to the respective dilute channels **24**. In other examples, amounts of the active monovalent cations in the second feed stream **14** may be greater than amounts of the removed target ions in the concentrate channels **25** when migrated from the concentrate channels **25** to the respective dilute channels **24**.

As a result, at least a larger portion of the active monovalent cations in the second feed stream **14** in the concentrate channels **25** may migrate through the cation exchange membrane **22** to enter into the adjacent dilute channel **24**. Accordingly, during operation, since the active monovalent cations in the second feed stream **14** may carry at least a larger portion of the ionic current than the removed target ions in the concentrate channels **25** when continuing to migrate from the concentrate channels **25** to the respective dilute channels **24** during operation, at least a larger portion of the removed target ions migrated into the concentrate channels **25** from the dilute channels **24** may not migrate through the cation exchange membranes **22** to further enter into the dilute channels **24** to remain in the respective concentrate channels **25** so as to increase the efficiency of the target ions removed from the first feed stream **13**.

For some arrangements, in order to increase the ionic current carried by the active monovalent cations in the second feed stream **14** when migrated into the dilute channels **24** from the concentrate channel **25**, as illustrated in FIG. 1, the desalination system **10** further comprises an ion adjustment unit **26** in fluid communication with the second feed stream **14** so as to facilitate that the ionic current carried by the active monovalent anions in the second feed stream **14** are greater than the ionic current carried by the target ions in the concentrate channels **25** when migrated from the concentrate channels **25** to the respective dilute channels **24**. In non-limiting examples, the active monovalent cations may include Na^+ , K^+ or H^+ . In one example, the ion adjustment unit **26** introduces sodium chloride solution into the second feed stream **14** to increase the concentration of the active monovalent ions, such as sodium ions (Na^+). In certain applications, the ion adjustment unit **26** may or may not be employed.

Accordingly, as depicted in FIG. 2, during operation, the second feed stream **14** passes through the concentrate channels **25** to carry at least a portion of the removed target anions, such as the hardness ions migrated from the dilute channels **24** out of the desalination apparatus **11**, so that the first output stream **15** having a suitable level of the hardness ions is then introduced into the EDI apparatus **12** for further processing.

In some examples, the polarity of the first and second electrodes **20**, **21** of the desalination apparatus **11** may be reversed. In the reversed polarity state, the dilute channels **24** from the normal polarity state may act as the concentrate channels to receive the second feed stream **14**, and the concentrate channels **25** from the normal polarity state may

7

function as the dilute channels to receive the first feed stream **13** for desalination, for example, for removal of the hardness ions in the first feed stream **13** and alleviation of the fouling tendency of the anions and cations in the desalination apparatus **11**.

It should be noted that the arrangements in FIG. **2** is merely illustrative. In some applications, the desalination apparatus **11** may be employed to remove different target ions using different active cations. In the illustrated example, the target ions to be removed at least include the hardness ions, and the active ions in the second feed stream **14** include Na^+ . In other examples, the active ions may include, but not limited to K^+ and H^+ .

FIG. **3** is an experimental graph illustrating hardness ion removal efficiency of the desalination apparatus **11** in accordance with one embodiment of the invention. In this experimental example, the desalination apparatus **11** comprises nine cation exchange membranes **22**. The DC voltage on the desalination apparatus **11** is about 5 volts. As illustrated in FIG. **3**, during continuous processing for about 50 minutes in the desalination apparatus **11**, the first feed stream **13** having a hardness of about 13 ppm is processed to produce the first output stream (product stream) **15** having a hardness of about 3 ppm.

Thus, about 77% of the hardness ions may be removed from the first feed stream and the hardness of the product stream **15** remains around 3 ppm during operation, which may indicate the desalination apparatus **11** has a relatively higher and stable remove efficiency of the hardness ions.

In the illustrated example in FIG. **1**, the desalination apparatus **11** and the EDI apparatus **12** are disposed separately. In other examples, as illustrated in FIG. **4**, the desalination apparatus **11** and the EDI apparatus **12** of the desalination system **10** may be disposed unitarily by using a common cathode and a common anode to act as a desalination apparatus **30**. The same numerals in FIGS. **1-2** and **4** may indicate similar elements. For easy illustration, some elements, for example the ion exchange resin are not illustrated in the arrangement in FIG. **4**.

As depicted in FIG. **4**, the desalination apparatus **30** comprises a first electrode **31**, a second electrode **32**, a plurality of ion exchange membranes **38**, **39**, **40**, and a plurality of spacers **33**. In the illustrated example, the first and second electrodes **31**, **32** are connected to positive and negative terminals of a power source (not shown) so as to act as an anode and a cathode, respectively.

In some applications, the first and second electrodes **31**, **32** may include electrically conductive materials. In non-limiting examples, the cathode may include stainless steel. The anode may include iridium oxide or platinum coated titanium. For some arrangements, the first and second electrodes **31**, **32** may be in the form of plates that are disposed parallel to each other to form a stacked structure. Alternatively, the electrodes may be arranged in varying configurations. For example, the first and second electrodes **31**, **32** may be disposed concentrically with a spiral and continuous space therebetween.

In the illustrated example, the ion exchange membranes are divided into first and second groups **36**, **37** disposed between the first and second electrodes **31**, **32** to form first groups of alternating first and second channels **34-35**, and second groups of alternating first and second channels **34'-35'** therebetween, which are also referred to as first and second groups of dilute and concentrate channels under operating conditions, respectively. In non-limiting examples, each of the first and second groups of the alter-

8

nating first and second channels may comprises a plurality of the alternating first and second channels.

The second group **37** is disposed between the first group **36** and the first electrode **31** so that the first channels **34'** of the second group of the first and second channels **34'-35'** are configured to receive a liquid from the first channel **34** of the first group of the first and second channels **34-35** in the first group **36** from further processing. One concentrate channel **35** is formed between the first and second groups **36**, **37**. Alternatively, the second group **37** may be disposed between the first group **36** and the second electrode **32**. Each of the ion exchange membranes of the first group **36** comprises a cation ion exchange membrane **38**. The second group **37** comprises a plurality of alternating cation and anion exchange membranes **39**, **40** so as to form the second group of the alternating dilute and concentrate channels **34'**, **35'**.

In some examples, each of the cation ion exchange membranes **38** of the first group **36** may comprise similar materials to the materials of the cation exchange membrane **22** in FIG. **2**. Non-limiting examples of the cation and anion exchange membranes **39**, **40** of the second group **37** include similar materials to the respective cation and anion exchange membranes in the electrodeionization (EDI) apparatus **12**.

In certain applications, during operation, in order to protect the ion exchange membrane of the second group **37**, for example, the anion exchange membrane **40**, which is disposed adjacent to the first group **36** to endure a higher pressure difference, the thickness of the anion exchange membrane **40** adjacent to the first group **36** may be thicker than the thickness of other ion exchange membranes, which are not adjacent to the respective electrodes **31**, **32**, in the first and second groups **36**, **37**. In non-limiting examples, the thickness of the anion exchange membrane **40** adjacent to the first group **36** may be in a range of from 1 mm to 3 mm, for example, 2 mm. In other examples, the membranes adjacent to the respective first and second electrodes **31**, **32** may also have a higher thickness, for example in a range of from 1 mm to 3 mm, such as 2 mm.

The spacers **33** are disposed between each pair of the adjacent ion exchange membranes, and between the first and second electrodes **31**, **32** and the respective adjacent membranes **38**, **39**. In some embodiments, the spacers **33** may also comprise any ion-permeable, electronically nonconductive material, including membranes and porous and nonporous materials.

Accordingly, similar to the arrangements in FIG. **2**, during operation, while an electrical current is applied to the desalination apparatus **30**, liquids, such as first feed stream **13** is introduced into the first (dilute) channel **34**. The second feed stream **14** is introduced into the second (concentrated) channels **35** in the first group **36** and between the first and second groups **36**, **37** respectively. As a result, at least a portion of target ions including, but not limited to hardness ions may be removed from the first feed stream **13** to produce a first output stream (a dilute stream) **15**. The second feed stream **14** carries at least a portion of the target ions removed from the first feed stream **13** out of the desalination device **30** during or after desalination of the first feed stream **13** to produce a second output stream (a concentrate stream) **16**.

Subsequently, similar to the EDI apparatus **12** shown in FIG. **1**, the first output stream **15** from the first group **36** is introduced into the dilute channels **34'** filled with the ion exchange resin (not shown) of the second group **37** for further removal of the target ions, such as the hardness ions so as to produce a product fluid **17** with a higher quality. Meanwhile, water splitting reactions occur in the ion

exchange resin in the dilute channels 34' for regeneration of the ion exchange resin. A third stream 18 from a liquid source (not shown) is introduced into the concentrated channels 35' of the second group 37 to carry the removed ions from the respective dilute channels 34' out of the desalination device 30 so as to produce a concentrate fluid 19.

It should be noted that the arrangement in FIG. 4 is merely illustrative. In the illustrated example, the EDI apparatus 12 is integrated with the desalination apparatus 11 shown in FIG. 1. Alternatively, other desalination apparatuses, such as electrodialysis (ED) apparatuses or electrodialysis reversal (EDR) apparatuses may also be disposed unitarily with the desalination apparatus 11 by using a common cathode and a common anode. Similarly, other target ions, including, but not limited to the hardness ions may also be removed. In some examples, the polarity of the first and second electrodes 31, 32 may be reversed.

In embodiments of the invention, the desalination apparatus 11 employs the cation ion exchange membranes to process a liquid for removal of the target ions, such as the hardness ions therein, which has stable and relatively higher removal efficiency. As a result, when the liquid having a suitable concentration level of the target ions is introduced into the EDI apparatus for further processing, the scaling or fouling issues may be avoided or alleviated so that the EDI apparatus sustains a continuous and stable operation. In addition, the desalination apparatus 11 may be disposed separately from or unitary with the EDI apparatus or other desalination apparatuses, which improves the system flexibility for processing of a liquid.

While the disclosure has been illustrated and described in typical embodiments, it is not intended to be limited to the details shown, since various modifications and substitutions can be made without departing in any way from the spirit of the present disclosure. As such, further modifications and equivalents of the disclosure herein disclosed may occur to persons skilled in the art using no more than routine experimentation, and all such modifications and equivalents are believed to be within the spirit and scope of the disclosure as defined by the following claims.

What is claimed is:

1. A desalination system, comprising:
 - a desalination apparatus, comprising:
 - first and second electrodes;
 - a first group of paired ion exchange membranes disposed between the first and second electrodes to form a first group of alternating first and second channels, the first channels configured to receive a first feed stream for desalination and the second channels configured to receive a second feed stream to carry away ions removed from the first feed stream, respectively; and
 - a plurality of spacers disposed between each pair of the adjacent ion exchange membranes and between the first and second electrodes and the respective ion exchange membranes,
 - wherein each of the ion exchange membranes in the first group is a cation exchange membrane; and
 - an electrodeionization apparatus configured to receive a stream from the first channels of the first group of the alternating first and second channels of the desalination apparatus for further processing.
2. The desalination system of claim 1, wherein the cation exchange membranes in the first group of the paired ion

exchange membranes comprise alternating normal cation exchange membranes and monovalent cation exchange membranes.

3. The desalination system of claim 1, further comprising an ion adjustment unit in fluid communication with the desalination apparatus and configured to increase amounts of active ions in the second feed stream.

4. The desalination system of claim 3, wherein the ion adjustment unit is configured to introduce sodium chloride solution into the second feed stream to increase the amounts of the active ions.

5. The desalination system of claim 1, wherein the desalination apparatus is configured to remove at least a portion of hardness ions in the first feed stream.

6. The desalination system of claim 1, wherein the desalination apparatus further comprises a second group of the paired ion exchange membranes disposed between the first group of the ion exchange membranes and at least one of the first and second electrodes to form a second group of the alternating first and second channels, and wherein the second group of the ion exchange membranes comprises a plurality of alternating cation and anion exchange membranes.

7. The desalination system of claim 6, wherein the desalination apparatus further comprises ion exchange resin filled into the first channels of the second group of the alternating first and second channels.

8. The desalination system of claim 6, wherein the first channels of the second group of the alternating first and second channels are configured to receive a liquid from the first channels of the first group of the alternating first and second channels.

9. A desalination system, comprising:

- a desalination apparatus configured to remove hardness ions from an aqueous stream, comprising:
 - first and second electrodes;
 - a first group of paired ion exchange membranes disposed between the first and second electrodes to form a first group of alternating first and second channels to receive a first feed stream for removal of the hardness ions and a second feed stream to carry away the hardness ions removed from the first feed stream, respectively;
 - a second group of the paired ion exchange membranes disposed between the first group of the ion exchange membranes and at least one of the first and second electrodes to form a second group of the alternating first and second channels; and
 - a plurality of spacers disposed between each pair of the adjacent ion exchange membranes and between the first and second electrodes and the respective ion exchange membranes,
- wherein each of the ion exchange membranes in the first group of the paired ion exchange membranes is a cation exchange membrane, and wherein the second group of the paired ion exchange membranes comprises a plurality of alternating cation and anion exchange membranes.

10. The desalination system of claim 9, wherein the first channels of the second group of the alternating first and second channels are configured to receive a liquid from the first channels of the first group of the alternating first and second channels.

11. The desalination system of claim 9, further comprising an ion adjustment unit in fluid communication with the desalination apparatus and configured to increase amounts of active ions in the second feed stream, and wherein the ion

11

adjustment unit is configured to introduce sodium chloride solution into the second feed stream to increase the amounts of the active ions.

12. The desalination system of claim 9, wherein a thickness of the ion exchange membrane of the second group of the paired ion exchange membranes adjacent to the first group of the ion exchange membranes is greater than a thickness of each of other ion exchange membranes nonadjacent to the first and second electrodes in the second group.

13. A method for removing ions from an aqueous stream, comprising:

passing a first feed stream through first channels of a first group of alternating first and second channels defined by a first group of paired cation exchange membranes of a desalination apparatus for removing at least a portion of cations to produce a first output stream;

passing a second feed stream through the second channels of the first group of the alternating first and second channels defined by the first group of the paired cation exchange membranes of the desalination apparatus to carry away the at least the portion of the cations removed from the first feed stream; and

passing the first output stream through an electrodeionization apparatus for further processing.

14. The method of claim 13, wherein the desalination apparatus comprises:

first and second electrodes;

the first group of the paired cation exchange membranes disposed between the first and second electrodes to form the first group of the alternating first and second channels; and

a plurality of spacers disposed between each pair of adjacent ion exchange membranes and between the first and second electrodes and the respective ion exchange membranes.

12

15. The method of claim 14, wherein the desalination apparatus further comprises a second group of paired ion exchange membranes disposed between the first group of the cation exchange membranes and at least one of the first and second electrodes to form a second group of the alternating first and second channels, and wherein the second group of the ion exchange membranes comprises a plurality of alternating cation and anion exchange membranes.

16. The method of claim 13, further comprising increasing amounts of active cations in the second feed stream before the second feed stream is introduced into the desalination apparatus.

17. The method of claim 15, wherein the desalination apparatus further comprises ion exchange resin filled into the first channels of the second group of the alternating first and second channels.

18. The method of claim 13, further comprising:

passing the first output stream through first channels of a second group of the alternating first and second channels defined by a second group of paired ion exchange membranes of the desalination apparatus for ion removal; and

passing a third stream through the second channels of the second group of the alternating first and second channels defined by the second group of the paired ion exchange membranes of the desalination apparatus to carry away ions removed from the first output stream.

19. The method of claim 13, further comprising

passing a third stream through the electrodeionization apparatus to carry away ions removed from the first output stream.
